Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

A large number of platinum compounds are known as hydrosilylation reaction catalysts. Among these, the platinum/alkenylsiloxane complex catalyst compositions as disclosed in Japanese Patent Publication Number 42-22924 (22,924/67) and Japanese Patent Publication Number 46-28795 (28,795/71) have a high catalytic activity and are useful as hydrosilylation reaction catalysts. These are prepared by a reaction, for example, between alkenyl group-containing siloxane and chloroplatinic acid.

However, this type of platinum catalyst composition generally suffers from a poor storage stability, and, unless careful attention is paid to its method of storage, it readily deteriorates into platinum black with a concomitant substantial loss in catalytic activity. For example, the catalyst suffers from a loss in activity within a few hours merely upon an increase in storage temperature. Moreover, its storage stability is also sharply reduced by other substances which may be compounded into the reaction system.

A large number of methods have been introduced in order to solve these problems. For example, Japanese Patent Publication Number 47-23679 (23,679/72) proposes that the storage stability be increased by removing the halide in the prepared platinum/alkenylsiloxane complex catalyst composition. In this method, the platinum/alkenylsiloxane complex catalyst composition is stored as such or in a neutral medium such as polysiloxane, and this represents an effective approach as long as the catalyst composition is placed in an environment free of temperature increases. However, this method is unsatisfactory with regard to the storage stability in the presence of non-neutral substances or in an environment suffering from temperature increases.

Japanese Patent Publication Numbers 46-28795 (28,795/71) and 46-29731 (29,731/71) disclose a platinum/alkenylsiloxane complex catalyst composition which is prepared using phenyl group-containing alkenylsiloxane. However, one encounters very low platinum-based yields in the preparation by conventional methods of platinum complex catalyst compositions having these phenyl-containing alkenylsiloxane ligands, and the problem then arises of poor economics.

In addition, Japanese Patent Application Laid Open (Kokai) Number 56-136655 (136,655/81) proposes a method for the preparation of a platinum/alkenylsiloxane complex catalyst composition via the bis-(1,5-cyclooctadiene)/Pt complex by ligand exchange with siloxane which contains the alkyl and alkenyl groups. Again, the economics of this method are poor due to the low yield of the intermediate bis-(1,5-cyclooctadiene)/Pt complex and due to the reduction in yield arising from the rapid decomposition to platinum black when this intermediate's solution comes into contact with the air.

FR-A 1 548 775 teaches platinum siloxane compositions which are used as catalyst for the hydrosilylation reaction. Moreover, US-A 3 775 452 teaches platinum complexes of unsaturated siloxanes and platinum-containing organopolysiloxanes useful as hydrosilylation catalysts. However, the heat stability of these known platinum complexes is not sufficient.

Thus, as discussed above, there have already been various attempts at improving the storage stability of Pt/alkenylsiloxane complex catalyst compositions. Nevertheless, aside from storage in a neutral medium in a low temperature ambient, no Pt/alkenylsiloxane complex catalyst composition has been discovered which evidences an excellent storage stability as well as good economics, nor has a method for the preparation of same been discovered.

A platinum catalyst composition having improved thermal stability is provided by mixing certain organosiloxanes which contain aryl and alkenyl groups, in a quantity of at least 2 moles, with a platinum complex having as a ligand an organosiloxane which contains alkyl and alkenyl groups, or a mixture of said platinum complex and said organosiloxane, in a quantity of 1 mole of platinum atoms.

The present invention relates to a platinum catalyst composition composed of (A) a platinum complex having as a ligand an organosiloxane which has no more than 8 silicon atoms in each molecule and contains alkyl and alkenyl groups and which has in each molecule at least one bond as represented by the following formula

wherein R¹ is an alkyl group having no more than 6 carbon atoms and R² is an alkenyl group, or a mixture of said platinum complex and said organosiloxane; and (B) an organosiloxane which contains aryl and alkenyl groups and has no more than 8 silicon atoms in each molecule and which contains in each molecule at least one bond as represented by the following formula

wherein R^3 is an aryl group and R^2 is defined as above, in a quantity of at least 2 moles of component (B) per 1 mole platinum atoms in component (A).

To explain this in greater detail, component (A) comprises a platinum complex having as ligand an organosiloxane which has no more than 8 silicon atoms in each molecule and contains alkyl and alkenyl groups and which has in each molecule at least one bond as represented by the following formula.

In the preceding formula R^1 is an alkyl group having no more than 6 carbon atoms such as methyl, ethyl, propyl, etc., and R^2 is an alkenyl group such as vinyl, allyl, etc.

Component (A) can also be the mixture of said platinum complex and said organosiloxane.

This component (A) may consist simply of the aforementioned platinum complex, but it may also be a mixture of said platinum complex with organosiloxane identical to or of the same type as the (alkyl + alkenyl)-containing organosiloxane coordinated in said platinum complex. (Alkyl + alkenyl)-containing organosiloxane not coordinated within the platinum complex should be present as a general matter at no more than 30 moles per 1 mole platinum atoms in the platinum complex.

This component (A) is in fact known, for example, as disclosed in Japanese Patent Publication Number 42-22924. In general, it is prepared by reacting, with heating, (alkyl + alkenyl)-containing siloxane with haloplatinic acid or haloplatinic acid salt. In the preparation of component (A) by this method, the alkenyl group in the starting (alkyl + alkenyl)-containing siloxane is generally the vinyl group. Moreover, it is preferred that the alkyl group be the methyl group considering the economics and prevention of side reactions during preparation of the platinum complex comprising component (A). Although no specific restriction is placed on groups which may be present in addition to the alkenyl and alkyl groups, it is necessary in particular to avoid aryl groups since this causes a reduction in the platinum yield in the preparation of component (A). Examples of this (alkyl + alkenyl)-containing siloxane are 1,3-divinyldimethylsiloxane and 1,3,5,7-tetravinyltetramethylcyclotetrasiloxane.

The (aryl + alkenyl)-containing siloxane comprising component (B) is the crucial component for increasing the stability of the platinum complex comprising component (A). In order to increase the stability of the platinum catalyst, this siloxane must contain no more than 8 silicon atoms in each molecule and must contain in each molecule at least one bond as represented by the next formula.

In the preceding formula R^3 is an aryl group such as phenyl, etc., and R^2 is an alkenyl group such as vinyl, allyl, etc. Such (aryl + alkenyl)-containing siloxanes are exemplified by 1,3-divinyl-1,3-diphenyldimethyldisiloxane and 1,3-divinyldiphenyldisiloxane.

Component (B) must be added in a quantity of at least 2 moles per 1 mole platinum atoms in component (A), and a stabilizing effect on the platinum catalyst comprising component (A) cannot be obtained at less than 2 moles.

The platinum catalyst composition of the present invention may be prepared by the method of this invention which comprises mixing the aforesaid components (A) and (B), in the amounts stated, and, optionally, then removing a portion of the (alkyl + alkenyl)-containing siloxane in component (A) by distillation in vacuo.

While the platinum catalyst composition of the present invention may be prepared according to either of these methods, preparation according to the latter method is preferred because it affords a more storage-stable platinum catalyst composition.

Thus, according to the latter method, a platinum catalyst composition with an even more superior storage stability is prepared by removal of part of the platinum-coordinated (alkyl + alkenyl)-containing organosiloxane and part or all of the non-platinum-coordinated (alkyl + alkenyl)-containing organosiloxane in component (A) and substitution with the (phenyl + alkenyl)-containing organosiloxane of component (B).

The platinum catalyst composition of the present invention has the same catalytic activity as prior platinum/siloxane complexes. However, the platinum catalyst composition of the present invention is distinguished by a better high-temperature stability and a better stability against other substances present in the system than the platinum/siloxane complexes known from the art.

Exploiting these distinguishing features, it can be used as a hydrosilylation reaction catalyst in the synthesis of silanes and siloxanes and also as a curing catalyst for those well-known organopolysiloxane compositions which cure by the hydrosilylation reaction.

Thus, the present invention further comprises a curable organopolysiloxane composition comprising the admixture of the platinum catalyst composition of this invention, at 0.1 to 100 parts by weight of platinum atoms, with a million parts by weight of a mixture of an organopolysiloxane having at least 2 alkenyl groups in each molecule and organohydrogenpolysiloxane having at least 2 silicon-bonded hydrogen atoms in each molecule.

The organopolysiloxane having at least 2 alkenyl groups in each molecule and the organohydrogenpolysiloxane having at least 2 silicon-bonded hydrogen atoms in each molecule can be any that are well-known in the organosilicon art.

The present invention is explained below by illustrative examples, in which parts is weight parts in all cases and the % platinum content refers to a weight%.

Example 1

200 Grams chloroplatinic acid (platinum content = 40%), 400 g 1,3-divinyldimethylsiloxane, 400 g sodium bicarbonate, and 1,000 g isopropyl alcohol were mixed and reacted with heating at 70 to 80 degrees Centigrade for 30 minutes. After removal of the produced salt by filtration, the isopropyl alcohol was removed in vacuo at 50 degrees Centigrade, and, after cooling, the precipitated salt was filtered off a second time. This afforded platinum catalyst composition (I) comprising 1,3-divinyldimethylsiloxane and a platinum complex having 1,3-divinyldimethylsiloxane as ligand. Its platinum content was 5.4%, and the platinum yield was 97.5%.

36 Grams 1,3-divinyl-1,3-diphenyldimethylsiloxane was added and mixed into 100 g platinum catalyst composition (I), and platinum catalyst composition (II) was then obtained by conducting distillation in vacuo at 4 Pa (0.03 torr) and 50 degrees Centigrade to remove the 1,3-divinyldimethylsiloxane. Its platinum content was 8.8%, and the platinum yield from platinum catalyst composition (I) was 99.2%. These platinum catalyst compositions were analyzed by nuclear magnetic resonance spectral analysis (NMR). Only a single peak at -6133 ppm was observed from platinum catalyst composition (I) by ¹⁹⁵Pt-NMR. On the other hand, in addition to the peak at -6133 ppm observed for platinum catalyst composition (I), platinum catalyst composition (II) gave a multiplet peak extending over -6080 to -6128 ppm, and the molar ratio between the two was 19%/81%. These results indicated that over 80% of the platinum in platinum catalyst composition (II) had been converted into a new complex from the platinum complex in platinum catalyst composition (I).

Platinum catalyst compositions (I) and (II) obtained as above were both diluted to a 2% platinum content by vinyl-terminated polydimethylsiloxane, and the decomposition temperature of the catalyst (temperature at which the transparent solution converted to brown) was measured at a temperature-rise rate of 1 degree Centigrade/minute.

Platinum catalyst composition (I) and platinum catalyst composition (II) were also respectively added at 1 ppm (platinum weight) to equimolar pentamethylsiloxane and 3-vinylheptamethyltrisiloxane. The reaction rates at 25 degrees Centigrade of the obtained siloxane compositions were measured by means of gas chromatography, and these results are reported in Table 1.

As these results make clear, platinum catalyst composition (II), which was prepared in accordance with the present invention, was more stable than platinum catalyst composition (I) while at the same time its catalytic activity remained unchanged.

Table 1

	present invention platinum catalyst composition (II)	comparison example platinum catalyst composition (I)
decomposition temperature	138°C	85°C

Table 1 (continued)

	present invention platinum catalyst composition (II)	comparison example platinum catalyst composition (I)
catalytic activity (half-life)	25 minutes	25 minutes

Comparison Example 1

Proceeding as for the synthesis of platinum catalyst composition (I) in Example 1, a platinum complex was prepared as in Example 1, but using 400 g 1,3-divinyldimethyltetramethyldisiloxane and 100 g 1,3-divinyl-1,3-diphenyldimethyldisiloxane in place of the 400 g 1,3-divinyldimethyltetramethyldisiloxane. However, the reaction rate was very slow, and platinum complex was not obtained by reaction for 30 minutes at 70 to 80 degrees Centigrade. The platinum yield did not exceed a maximum of 56% during reaction with heating for 60 minutes. When the heated reaction was conducted for longer periods of time, the platinum yield after final filtration fell off due to an increase in platinum black production, and it declined to 35% after 120 minutes.

Moreover, when a platinum catalyst composition was prepared as in Example 1 by replacing the 1,3-divinyldimethyltetramethyldisiloxane in Example 1 with 1,3-divinyl-1,3-diphenyldimethyldisiloxane, the reaction rate was even slower and the maximum platinum yield was also reduced.

The preceding makes clear that the platinum yield is sharply reduced when a (phenyl + vinyl)-containing organosiloxane is simultaneously present in the synthesis of the alkenyl/Pt complex.

Example 2

Platinum catalyst composition (II) as obtained in Example 1 was mixed to give 5 ppm as the weight of platinum into 100 parts vinyl-terminated dimethylpolysiloxane (viscosity = 12,000 mm²/s) to prepare a mixture. Curable organopolysiloxane compositions were obtained by the addition to such a mixture, either immediately after mixing or after its ageing for 2 weeks at 70 degrees Centigrade, of 0.9 parts methylhydrogenpolysiloxane with the average structural formula

and 0.02 parts methylbutynol. The curing performance was then measured as the gelation time at 130 degrees Centigrade, and these measurement results are reported in Table 2. For comparison, curable organopolysiloxane compositions were prepared as above, but using platinum catalyst composition (I) in place of platinum catalyst composition (II). The curing performance of these compositions was also measured as above, and these results again are reported in Table 2.

These measurement results make it clear that the platinum catalyst composition of the present invention has a high storage stability.

Table 2.

	present invention	comparison example
immediately after mixing	30 seconds	29 seconds
after ageing	29 seconds	97 seconds

Example 3

A platinum catalyst composition (III) was prepared by the addition with mixing to homogeneity of 3.0 g 1,3-divinyl-1,3-diphenyldimethyldisiloxane to 10 g platinum catalyst composition (I) as prepared in Example 1.

Using this platinum catalyst composition (III) in place of the platinum catalyst composition (II) used in Example 2, a curable organopolysiloxane composition was then prepared proceeding otherwise the same as in Example 2.

The curing performance of this composition was measured as in Example 2: the gelation time at 130 degrees Centigrade was 33 seconds for the curable organopolysiloxane composition which used the platinum catalyst composition immediately after mixing, while the gelation time at 130 degrees Centigrade was 31 seconds for the curable

organopolysiloxane composition which used the aged platinum catalyst composition.

As discussed above, because the platinum catalyst composition of the present invention consists of component (A) and component (B), it is distinguished by an excellent storage stability. Moreover, the preparative method of the present invention is distinguished by the inexpensive and highly productive preparation of the platinum catalyst composition under consideration.

Furthermore, the curable organopolysiloxane composition which contains said platinum catalyst composition is itself distinguished by an excellent storage stability.

Claims

1. A platinum catalyst composition comprising

(A) a platinum complex having as a ligand an organosiloxane which has no more than 8 silicon atoms in each molecule and contains alkyl and alkenyl groups and which has in each molecule at least one bond as represented by the formula

wherein R¹ is an alkyl group having no more than 6 carbon atoms and R² is an alkenyl group, or a mixture of said platinum complex and said organosiloxane; and

(B) an organosiloxane which contains aryl and alkenyl groups and has no more than 8 silicon atoms in each molecule and which contains in each molecule at least one bond as represented by the formula

wherein R³ is an aryl group and R² is defined as above, in a quantity of at least 2 moles of component (B) per 1 mole platinum atoms in component (A).

2. A platinum catalyst in accordance with claim 1 in which the organopolysiloxane of component (A) is 1,3- divinyltetramethyldisiloxane and component (B) is 1,3- divinyl-1,3-diphenyldimethyldisiloxane.

3. A platinum catalyst in accordance with claim 1 further comprising a platinum complex having as a ligand an organosiloxane which has no more than 8 silicon atoms in each molecule and contains aryl and alkenyl groups and which contains in each molecule at least one bond as represented by the formula

wherein R³ is an aryl group and R² is an alkenyl group.

4. A method for the preparation of a platinum catalyst composition, said method comprising mixing

(A) a platinum complex having as a ligand an organosiloxane which has no more than 8 silicon atoms in each molecule and contains alkyl and alkenyl groups and which has in each molecule at least one bond as represented by the formula

wherein R¹ is an alkyl group having no more than 6 carbon atoms and R² is an alkenyl group, or a mixture of said platinum complex and said organosiloxane; and

(B) an organosiloxane which contains aryl and alkenyl groups and has no more than 8 silicon atoms in each molecule and which contains in each molecule at least one bond as represented by the formula

wherein R³ is an aryl group and R² is defined as above, in a quantity of at least 2 moles of component (B) per 1 mole platinum atoms in component (A).

5. A curable organopolysiloxane composition comprising the admixture of the platinum catalyst composition of claim 1, at 0.1 to 100 parts by weight of platinum atoms, with a million parts by weight of a mixture of an organopolysiloxane having at least 2 alkenyl groups in each molecule and organohydrogenpolysiloxane having at least 2 silicon-bonded hydrogen atoms in each molecule.

Patentansprüche

1. Platinkatalysatorzusammensetzung dies

(A) einen Platinkomplex mit einem Organosiloxan, das nicht mehr als 8 Siliciumatome in jedem Molekül aufweist und Alkyl- und Alkenylgruppen enthält und in jedem Molekül mindestens eine Bindung der folgenden Formel besitzt:

worin R¹ für eine Alkylgruppe mit nicht mehr als 6 Kohlenstoffatomen steht und R² eine Alkenylgruppe bedeutet, als Liganden oder ein Gemisch aus dem Platinkomplex und dem Organosiloxan und

(B) ein Organosiloxan, das Aryl- und Alkenylgruppen enthält und nicht mehr als 8 Siliciumatome in jedem Molekül aufweist und in jedem Molekül mindestens eine Bindung der folgenden Formel besitzt:

worin R^3 für eine Arylgruppe steht und R^2 die oben angegebene Bedeutung besitzt, in einer Menge von mindestens 2 Molen Komponente (B) pro 1 Mol Platinatome in Komponente (A) umfaßt.

2. Platinkatalysator nach Anspruch 1, in dem das Organopolysiloxan der Komponente (A) aus 1,3-Divinyltetramethyldisiloxan und die Komponente (B) aus 1,3-Divinyl-1,3-diphenyldimethyldisiloxan bestehen.
3. Platinkatalysator nach Anspruch 1, der des weiteren einen Platinkomplex mit einem Organosiloxan, das nicht mehr als 8 Siliciumatome in jedem Molekül aufweist und Aryl- und Alkenylgruppen enthält und in jedem Molekül mindestens eine Bindung der folgenden Formel enthält:

worin R^3 für eine Arylgruppe steht und R^2 eine Alkenylgruppe bedeutet, als Liganden umfaßt.

4. Verfahren zur Herstellung einer Platinkatalysatorzusammensetzung durch Vermischen

(A) eines Platinkomplexes mit einem Organosiloxan, das nicht mehr als 8 Siliciumatome in jedem Molekül aufweist und Alkyl- und Alkenylgruppen enthält und in jedem Molekül mindestens eine Bindung der folgenden Formel aufweist:

worin R^1 für eine Alkylgruppe mit nicht mehr als 6 Kohlenstoffatomen steht und R^2 eine Alkenylgruppe bedeutet, als Liganden oder eines Gemisches aus dem Platinkomplex und dem Organosiloxan und (B) eines Organosiloxans, das Aryl- und Alkenylgruppen enthält und nicht mehr als 8 Siliciumatome in jedem Molekül aufweist und in jedem Molekül mindestens eine Bindung der folgenden Formel besitzt:

worin R^3 für eine Arylgruppe steht und R^2 die oben angegebene Bedeutung besitzt, in einer Menge von mindestens 2 Molen Komponente (B) pro 1 Mol Platinatome in Komponente (A).

5. Härtbare Organopolysiloxanzusammensetzung, die ein Gemisch aus der Platinkatalysatorzusammensetzung von Anspruch 1 in einer Menge von 0,1 bis 100 Gew.-Teilen an Platinatomen zusammen mit 1 Million Gew.-Teilen eines Gemisches eines Organopolysiloxans mit mindestens 2 Alkenylgruppen in jedem Molekül und eines Organohydrogenpolysiloxans mit mindestens 2 siliciumgebundenen Wasserstoffen in jedem Molekül umfaßt.

Revendications

1. Composition de catalyseur au platine, comprenant

(A) un complexe du platine ayant en tant que ligand un organosiloxane qui n'a pas plus de 8 atomes de silicium dans chaque molécule et contient des groupes alkyles et alcényles, et qui a dans chaque molécule au moins une liaison telle que représentée par la formule

dans laquelle R¹ est un groupe alkyle n'ayant pas plus de 6 atomes de carbone et R² est un groupe alcényle, ou un mélange dudit complexe de platine et dudit organosiloxane ; et

(B) un organosiloxane qui contient des groupes aryles et alcényles et n'a pas plus de 8 atomes de silicium dans chaque molécule, et qui contient dans chaque molécule au moins une liaison telle que représentée par la formule

dans laquelle R³ est un groupe aryle et R² est tel que défini ci-dessus, en une proportion d'au moins 2 moles de constituant (B) pour 1 mole d'atomes de platine dans le constituant (A).

2. Catalyseur au platine selon la revendication 1, dans laquelle l'organopolysiloxane du constituant (A) est le 1,3-divinyltétraméthylidisiloxane et le constituant (B) est le 1,3-divinyl-1,3-diphényldiméthylidisiloxane.
3. Catalyseur au platine selon la revendication 1, comprenant en outre un complexe du platine ayant en tant que ligand un organosiloxane qui n'a pas plus de 8 atomes de silicium dans chaque molécule et contient des groupes aryles et alcényles, et qui contient dans chaque molécule au moins une liaison telle que représentée par la formule

dans laquelle R³ est un groupe aryle et R² est un groupe alcényle.

4. Procédé pour la préparation d'une composition de catalyseur au platine, ledit procédé comprenant le mélange

(A) d'un complexe du platine ayant en tant que ligand un organosiloxane qui n'a pas plus de 8 atomes de silicium dans chaque molécule et contient des groupes alkyles et alcényles, et qui a dans chaque molécule au moins une liaison telle que représentée par la formule

dans laquelle R¹ est un groupe alkyle n'ayant pas plus de 6 atomes de carbone et R² est un groupe alcényle, ou d'un mélange dudit complexe de platine et dudit organosiloxane ; et

(B) d'un organosiloxane qui contient des groupes aryles et alcényles et n'a pas plus de 8 atomes de silicium dans chaque molécule, et qui contient dans chaque molécule au moins une liaison telle que représentée par la formule

dans laquelle R³ est un groupe aryle et R² est tel que défini ci-dessus, en une proportion d'au moins 2 moles de constituant (B) pour 1 mole d'atomes de platine dans le constituant (A).

5. Composition d'organopolysiloxanes durcissable, comprenant le mélange de la composition de catalyseur au platine selon la revendication 1, à raison de 0,1 à 100 parties en poids d'atomes de platine, avec un million de parties en poids d'un mélange d'un organopolysiloxane ayant au moins 2 groupes alcényles dans chaque molécule et d'un organohydrogénopolysiloxane ayant au moins 2 atomes d'hydrogène liés au silicium dans chaque molécule.
